

Dead bugs don't lie.

Unfortunately, sometimes sterilizers do. That's why monitors are so important—and why, even though we offer chemical indicators, we still recommend using a biological indicator.

What's the difference? Well, a chemical indicator is not a living organism. So, while it can tell you a lot about process time and temperature, it can't provide a direct measure of lethality.

A biological indicator tells you that resistant micro-organisms have been killed.

Seeing is believing, after all.
